Introduction

Antiya Tall is a water reservoir receiving municipal waste water and sewage from Jhansi city. Lakes are stagnant surface water bodies, receive and stores rain fall water. Stagnant water bodies have more complex and fragile ecosystem in comparison to running water bodies as they lack self cleaning ability and hence readily accumulate great quantities of pollutants. Increased anthropogenic activities in and around the water bodies damage the aquatic ecosystems and ultimately the physico chemical properties of water (Upadhyay et al., 2010).

The urban aquatic ecosystems are strongly influenced by long term discharge of untreated domestic and industrial wastewaters, storm water runoff, accidental spills and direct solid waste dumping (Sarika and Chandramohankumar,2008) .Generally speaking, water pollution is a state of deviation from pure condition, where by its normal functioning and properties are affected. Aggravated environmental problems often reflected the misuse or misunderstanding of technology (Petak, 1980).

Water quality degradation by various sources becomes an important issue around the world. Usage of more land for agricultural purposes, soil salinization, and increase in the use of agricultural fertilizers, common pesticide use, and erosion have become problems threatening natural water source (Zalids et al., 2002).

The physical and chemical limnology of a lake is characterized by hydrologic impact, autogenic nutrient dynamics and biological aspects. These factors combine with each other determine the water quality and consequently community of lake (Sidneit et al., 1992). The increased demand of water as a consequence of population growth, agriculture and industrial development has forced environmentalist to determine the chemical, physical and biological characteristics of natural water resources (Regina and Nabi, 2003).

To study the extent of pollution in surface water we have selected the Antiya Tall, which is subjected to enormous anthropogenic stresses; receive heavy inputs of domestic waste and sewage. The overall objective of this study is to evaluate the physico-chemical characteristics of Tall water and degree to which the heavy metal contamination has affected the tall water quality.

Materials and Methods

Antiya Tall is located between latitude 25^o 12' N-12^o 16' N and longitude 78^o 18' E-78^o 23'E in Jhansi City, Bundelkhand region, Central India. Tall is shallow with an area of 0.32 Km² and is surrounded by residential houses in all sides. The increased anthropogenic activities in the adjacent catchment area caused increased inflow of untreated sewage, municipal solid wastes, nutrients and pesticides from urban dwellings thereby deteriorating the water quality of the lake. The study was conducted during the period of January 2010 to June 2010 to explore the physico-chemical characteristics of Tall water and heavy metal contamination. Sub surface sampling was carried out from three sites of Antiya Tall and samples were analyzed immediately for parameters, which need to be determined instantly and rest of samples were refrigerated at 4°C to be analyzed later (Sharma et al.,2010). For the estimation of DO and BOD, water samples were fixed at the sites. Physico-chemical analysis of water was carried out referring the 'standard methods 2002'.

Results and Discussion

Temperature and photoperiod are important factors which control the behavior, physiology and distribution of organism (Srivastav et al., 2009). The average values of water temperature at all three sites were ranged between $32\pm1^{\circ}$ C (June) and $16\pm1^{\circ}$ C (January). Temperature was found negatively correlated with DO (Das, 2000) and positively correlated with turbidity (Pradhan et al., 2003). Temperature also represents a positive correlation with BOD and COD.

In the present study pH is negatively correlated with temperature. The average pH values at all three sites were found to be ranged between 7.3 ± 0.15 (June) to 9.7 ± 0.15 (January). The Tall water represents alkaline pH throughout the study period.

Water Transparency is an important factor that controls the energy relationship at different trophic levels. It is essentially a function of reflection of light from the surface and is influenced by the absorption characteristics of both water and of its dissolved and particulate matter (Stepane et al., 1959). Turbidity is positively correlated with temperature. The range of turbidity variation was found between 34 ± 2.6 NTU (January) and 63.33 ± 4.1 NTU (June) at all the sites.

Total Dissolved Solid signify the inorganic pollution load of a water system (Usha et al.,2008). The average values of Total Dissolved Solid at all sampling sites were ranged between 765.66+70.50 mg/l (January) and 1153.33±77.51 mg/l (June).

DO concentration decreases in water during summer season due to decreased rate of oxygen diffusion from atmosphere to water. DO is negatively correlated with temperature, BOD and COD. The average values of DO at all three sites were varied from 3.03 ± 0.07 mg/l (January) to 1.1 ± 0.04 mg/l (June).

BOD is oxygen requirement of microorganism during decomposition of biodegradable organic matter. It represents a significant positive correlation with temperature and COD. The

average values of BOD at all three sites were ranged between 5.29±0.03 mg/l (January) and 9.11±0.8 mg/l (June).

COD is an oxygen demand to decompose the biodegradable as well as non biodegradable organic waste. The average values of COD at all three sites were found to be ranging from 25.39 ± 11.27 mg/l (January) to 63.95 ± 13.8 mg/l (June).

Total alkalinity is due to salts of weak acids and bicarbonates to highly alkaline water is unportable (Mahadev et al., 2010). High values of total alkalinity may be attributed to the increase in organic decomposition during which CO₂ is liberated (Bharathi et al., 1973). This reacts to form bicarbonate thereby increasing total alkalinity in summer. The average values of total alkalinity at all three sites were recorded to be ranging from 283.33 \pm 30.05 mg/l (January) to 495.67 \pm 26.01 mg/l (June).

Hardness mainly causes from cations and of Ca⁺⁺, Mg⁺⁺, Sr⁺⁺, Fe⁺⁺ [14]. The average values of Total Hardness were ranged between 453.33 ± 86 mg/l (January) and 650 ± 149 mg/l (June) at all three sites.

The average chloride values from all three sites were oscillated between 29.66 ± 5.6 mg/l to 81 ± 9.6 mg/l from January to June. The average values of fluoride during the study period at all site were ranged between 0.8 ± 0.1 mg/l (January) to 2.6 ± 0.43 mg/l (June).

Nitrate in its average concentration at all three sites was ranged between 15 ± 1 mg/l (January) and 30 ± 2.00 mg/l (June) during the study period. Presence of nitrate in water indicates the final stage of mineralization (Nema et al., 1984).

The physical, chemical and biological processes occurring permanently in an aquatic environment should be considered to explain the inorganic elements and heavy metals concentration (Nguyen et al., 1998). External processes like discharging of pollutants and anthropogenic activities also affect the concentration and behavior of inorganic elements and heavy metals concentration (Baeyens et al., 1998). The average value of lead was reported in range of 0.25 ± 0.05 mg/l (January) 0.75 ± 0.09 mg/l (June). The average values of cadmium were found to be ranged between 0.22 ± 0.14 mg/l (January) to 0.57 ± 0.06 mg/l (June), iron between 3.06 ± 0.51 mg/l (January) to 4.7 ± 0.34 mg/l (June) and chromium between 0.79 ± 0.03 mg/l(January) to 1.39 ± 0.03 mg/l(June) at all three sites.

The average values of monthly variation in physicochemical parameters of water collected from different sites of the lake are shown in table-1 and their correlation in table-2.

Conclusion

The present study of physico-chemical characteristics of Antiya Tall water reveals that the pond is tending towards the deterioration because the concentration of inorganic elements and heavy metals were not found within the safe limit at the sampling site throughout the study period due to excessive dumping of municipal waste water and sewage. Therefore there is an urgent need of regular monitoring of water quality to govern the status.
